

OpenSIPS Repository Demand Report

Repository usage, package downloads, distribution demand, and OpenSIPS version adoption

Analysis window

30 April 2023 - 1 September 2026

Primary comparison windows

Last 12 months: 1 September 2025 - 1 September 2026

Last 3 months: 1 June 2026 - 1 September 2026

Source

Nginx access logs from apt.opensips.org, yum.opensips.org, and download.opensips.org

Prepared 1 September 2026

KEY FINDINGS

Executive summary

64.2M access-log lines analyzed	14,861 APT IPs active in 12 months	4,651 RPM IPs active in 12 months	233.2 GiB packages served in 12 months
---	--	---	--

Demand is concentrated around a clear core: Debian 12 and 11, Ubuntu 24.04 and 22.04, and Enterprise Linux 8, 9, and 7. OpenSIPS 3.4 still has a large installed base, 3.6 leads recent activity, and 4.0 is gaining APT adoption quickly.

- Highest-priority distributions: Debian 12/11 and Ubuntu 24.04/22.04; EL 8/9 remain important, while EL 7 still has too much traffic to dismiss.
- Version direction: 3.6 has overtaken 3.4 in recent APT activity. OpenSIPS 4.0 is already visible on Debian, but RPM adoption is still very small.
- Low-demand targets: Fedora and CentOS Stream are materially smaller than EL and the main Debian/Ubuntu distributions.
- Legacy tail: Ubuntu 18.04/20.04, Debian 10, and OpenSIPS 2.4-3.2 remain non-zero, but are small relative to the supported core.
- Download behavior: HTTP, TLS, authentication, and MySQL packages are the most widely fetched modules.

Important interpretation: unique IP is an upper-bound proxy for users, not an account count. NAT can combine many users into one IP, while cloud fleets can make one organization appear as hundreds of IPs. Base-package downloads are therefore used as the stricter installation/update signal.

HOW TO READ THE NUMBERS

Methodology and data quality

The analysis classified requests by host, repository path, operating-system family and version, OpenSIPS series, repository channel, package filename, HTTP status, and user-agent. It kept metadata checks separate from actual package transfers.

Metric	Definition	Best use
Active IP	Distinct source IP that made a successful, branch-specific metadata request with a package-manager user-agent.	Upper-bound repository reach.
Base-package downloader	Distinct IP that received the primary opensips .deb or .rpm package with HTTP 200/206.	Stricter installation or update signal.
Package transfer	Successful transfer of any .deb, .ddeb, or .rpm file, including modules and repeat updates.	Repository volume and module demand.
Missing-repository demand	Package-manager request that matched a repository path but returned HTTP 404.	Identify stale configurations and unsupported combinations.

Filtering and estimation

- Only characteristic APT, DNF, YUM, libdnf, urlgrabber, Zypper, PackageKit, and related user-agents were accepted for repository activity.
- Known crawler and scanner user-agents were excluded from direct source-download statistics. Checksum requests were not treated as downloads.
- Distinct IP counts use HyperLogLog with approximately 1.6% expected statistical error.
- Counts are not additive across rows because an IP may access multiple distributions or OpenSIPS branches.

A large June 2026 Debian 12 / OpenSIPS 3.5 spike was traced to one automation pattern fetching the same Packages.gz from hundreds of short-lived AWS addresses. It used Debian APT 2.6.1 and is reported as fleet/CI activity, not as equivalent independent users.

UNIQUE REPOSITORY IPS

Distribution demand

Estimated unique IPs over the last 12 months. Debian 12 includes the identified AWS fleet effect, especially in the last-three-month view.

Distribution	12 months	3 months	Assessment
Debian 12 Bookworm	6,117	2,785*	Largest reach; 3-month figure inflated by AWS fleet
Debian 11 Bullseye	4,450	2,110	Large and still very active
Ubuntu 24.04 Noble	2,291	549	Strong current target
Ubuntu 22.04 Jammy	2,001	941	Strong installed base
Enterprise Linux 8	1,584	686	Core RPM platform
Enterprise Linux 9	1,497	708	Core RPM platform; strongest recent EL
Enterprise Linux 7	1,385	402	Legacy OS, but meaningful demand remains
Debian 13 Trixie	326	290	Small but almost entirely recent
Debian 10 Buster	308	67	Declining legacy tail
Ubuntu 20.04 Focal	269	50	Declining legacy tail
CentOS Stream 8 / 9	191 / 147	97 / 70	Low relative to EL
Ubuntu 26.04 Resolute	96	94	New, early-stage demand
Ubuntu 18.04 Bionic	65	19	Very small legacy tail
Fedora 36 / 38 / 40	12-20 each	4-10 each	Lowest-demand maintained family

RELEASE REPOSITORIES

OpenSIPS version demand

Version	APT 12m	APT 3m	RPM 12m	RPM 3m	Interpretation
3.4	5,502	1,623	1,436	614	Largest established base
3.6	4,567	2,150	655	286	Leads recent APT activity
3.5	3,423*	1,924*	467	135	APT reach distorted by AWS fleet
4.0	816	809	33	30	Rapid APT uptake; RPM still minimal
3.3	531	94	870	395	Small APT tail; material RPM base
3.2	309	70	1,111	358	Legacy RPM demand remains
3.1	248	50	516	211	Legacy tail
2.4	180	small	-	-	Low but non-zero APT tail

Monthly package-download reach

Unique APT IPs downloading any package in each branch during 2026. These figures reflect release and update cadence, not only installed base. The July-August 4.0 increase is nevertheless clear.

The main directional signal is migration upward: 3.6 has become the strongest recent APT branch, while 4.0 moved from almost no package-download reach in May to 462 IPs in July and 356 in August. RPM adoption of 4.0 remains negligible.

STRICTER INSTALLATION/UPDATE SIGNAL

Actual package downloads

The table compares branch-specific repository reach with IPs that actually downloaded the primary opensips package during the last 12 months.

Distribution / OpenSIPS	Active IPs	Base-package IPs	Conversion signal
Debian 12 / 3.6	2,127	1,920	Very strong
Debian 12 / 3.4	2,016	1,397	Strong established base
Ubuntu 24.04 / 3.6	1,100	833	Strong
Ubuntu 22.04 / 3.4	1,393	770	Strong established base
Debian 11 / 3.4	1,172	563	Material installed base
Debian 12 / 3.5	1,980*	516	Metadata reach inflated by fleet activity
Debian 11 / 4.0	631	507	Strong early 4.0 workload
Ubuntu 24.04 / 3.4	968	501	Material installed base
Debian 11 / 3.6	975	410	Material
Debian 11 / 3.5	940	327	Moderate
Ubuntu 22.04 / 3.6	383	305	Strong conversion
Debian 12 / 3.3	287	272	Small but real legacy workload
Ubuntu 24.04 / 3.5	364	231	Moderate
EL 9 / 3.6	399	163	Leading newer RPM combination
EL 9 / 3.4	618	142	Large polling base, fewer package fetches
EL 7 / 3.4	421	132	Legacy OS still active

Window	APT transfers	APT IPs	RPM transfers	RPM IPs	Traffic
Last 12 months	349,660	11,009	44,489	1,162	233.2 GiB
Last 3 months	83,039	4,066	8,350	271	51.6 GiB
Full log period	950,873	23,964	150,020	4,290	666.8 GiB

Transfer counts include modules, repeat updates, and debug packages. Distinct IPs are deduplicated within each platform and window.

WHAT USERS FETCH - AND WHAT KEEPS FAILING

Package mix and legacy demand

Most widely downloaded optional packages in OpenSIPS 3.6 and 3.4 during the last 12 months:

Package family	3.6 unique IPs	3.4 unique IPs	Demand signal
HTTP modules	2,990	2,034	Highest optional package reach
TLS management	2,565	2,115	Core operational dependency
MySQL	2,383	1,776	Most-used database module
Authentication modules	2,369	2,135	Consistently high
TLS	2,351	2,026	Consistently high
TLS OpenSSL	2,348	1,943	Consistently high
REST client	1,860	1,444	Strong integration demand
JSON	1,777	1,644	Strong integration demand

Requests to missing or retired repositories

Missing combination	Unique IPs, 12m	Requests, 12m	Interpretation
Ubuntu Trusty / 2.3	131	68,533	Small set of stale systems
Ubuntu Trusty / 3.0	126	35,802	Small set of stale systems
Ubuntu Trusty / 2.2	83	111,775	Persistent retry traffic
EL 7 / 2.4	61	55,622	Legacy configuration
Ubuntu Xenial / 2.2	24	284,674	Very high retry rate from few IPs
EL 6 / 2.2	22	509,342	Very high retry rate from few IPs
Debian Jessie / 2.4	17	51,814	Small legacy tail
Debian Stretch / 2.4	12	56,713	Small legacy tail

Old source tarballs are disproportionately popular: for example, 2.4.0 reached 129 IPs in 12 months versus 100 for 3.6.6. This pattern is consistent with mirrors and automated archival crawlers, so source-tarball counts should not drive support decisions.

RECOMMENDED PRIORITIZATION

Operational conclusions

Priority	Recommendation	Evidence
1	Keep Debian 12/11 and Ubuntu 24.04/22.04 at the center of build, CI, and documentation coverage.	They dominate both active repository reach and base-package downloads.
2	Maintain strong EL 8/9 coverage, and avoid retiring EL 7 solely on age.	EL 7 still reached about 1,385 IPs in 12 months and 402 in 3 months.
3	Treat both OpenSIPS 3.4 and 3.6 as first-class branches for now.	3.4 has the largest established base; 3.6 leads recent APT activity and downloads.
4	Prepare for continued 4.0 APT growth while monitoring RPM adoption separately.	4.0 reached 809 APT IPs in 3 months, but only 30 RPM IPs.
5	Review the cost-benefit of Fedora and, secondarily, CentOS Stream packaging.	Fedora versions reached only 12-20 IPs each in 12 months; Stream reached 147-191.
6	Do not interpret raw request totals as popularity.	YUM clients generate far more repeated metadata traffic per IP than APT clients.
7	Add monthly aggregation by ASN or network prefix alongside unique IPs.	This will reduce inflation from cloud fleets and make organization-level demand easier to estimate.
8	Return cacheable EOL guidance for retired repository paths.	A few stale systems generate hundreds of thousands of repeated 404 requests.

Bottom line

The most defensible current product signal is: prioritize Debian and Ubuntu, preserve meaningful EL coverage including EL 7, keep 3.4 and 3.6 fully supported, and expect 4.0 demand to expand first through APT. Fedora is the clearest low-demand packaging target. Legacy repositories still receive traffic, but mostly from small numbers of stale systems rather than a broad user base.

Notes: all counts are derived from server access logs and are estimates, not account-level analytics. The September 2026 endpoint includes only 1 September. No server configuration or log files were modified during the analysis.
